

ABSTRACT

The present invention is constructed such that in a sliding screen door in which a net is formed to be capable of expansion and contraction by being alternately folded back in a reverse direction, and is formed to be capable of freely opening and closing by horizontal pulling, a net guide for guiding the aforementioned net is formed to be able to form the net guide into a straight line-shape in a condition of being led out from a frame member, and a movement of a net-holding member that follows the net guide is made smooth, and many of the guiding elements form the net guide 12 for guiding the lower end of the net, which is moved out from and into an interior of a vertical frame member 6, from the lower end of the vertical frame member 6 that is attached to both ends of the net in an open and close direction in response to the open-and-close movement of the net, into an approximately U-shape composed of a bottom portion and rising wall portions, and are mutually and flexibly connected by means of inserting a series of wire members 16 into through holes that follow a tip end portions of the rising wall portions, and are formed into a series of guide rail that is serially in contact with each other by means of rising wall portions of the adjoining guiding elements, and that in the sliding screen door, a

net-holding member 20 which is engaged with the
aforementioned guide rail in a manner so as to be movable
along the guide rail, and which suppresses an end portion of
the net to be disengaged from the net guide by means of
directly or indirectly holding the end portion of the net is
provided in the aforementioned guide rail.
